

Abstract

In accordance with the present invention, an optical device is provided that includes an $N \times N$ network, where N is an integer greater than or equal to 2. The network has N input ports for receiving optical input energy and N output ports for providing optical output energy. The optical output energy at each of the output ports arises from interference among the optical input energy received at the input ports. $(N-1)$ feedback paths optically couple $(N-1)$ of the input ports of the $N \times N$ network to $(N-1)$ of the output ports of the $N \times N$ network. A first optical waveguide, which is provided for receiving an input optical signal, is coupled to a remaining one of the input ports of the $N \times N$ network. A second optical waveguide, which is provided for the exit of an output optical signal, is coupled to a remaining one of the output ports of the $N \times N$ network. Finally, an active element is provided which selectively supplies gain or loss to optical energy in at least one of the feedback paths. The optical device may be employed as a dispersion compensator or an amplifier.
